Introduction

This document gives overview of the algorithms implemented in Quantum Wave ToolBox (QWTB).

Toolbox was realized within the EMRP-Project SIB59 Q-Wave. The EMRP is jointly funded by the EMRP participating countries within EURAMET and the European Union.

ADEV – Allan Deviation

Description

.id — ADEV

.name — Allan Deviation

.desc — Compute the Allan deviation for a set of time-domain frequency data.

.citation — D.W. Allan, "The Statistics of Atomic Frequency Standards", Proc. IEEE, Vol. 54, No. 2, pp. 221-230, Feb. 1966. Implementation by M. A. Hopcroft, mhopeng@gmail.com, Matlab Central, online: <http://www.mathworks.com/matlabcentral/fileexchange/13246-allan> Test data by W. J. Riley, "The Calculation of Time Domain Frequency Stability", online: <http://www.wiley.com/paper1ht.htm>

.remarks — If tau is empty array, tau values are automatically generated. Tau values must be divisible by 1/fs. Invalid values are ignored. For tau values really used in the calculation see the output. Using sigma as uncertainty is probably not correct.

.license — BSD License

.requires

y — sampled values

fs — sampling frequency

tau — observation time

.returns

adev — Allan deviation

tau — observation time of result values

.providesGUF — yes
.providesMCM — no

Example

Allan Deviation

Example for algorithm ADEV.

ADEV is an algorithm to compute the Allan deviation for a set of time-domain frequency data.

See also W. J. Riley, "The Calculation of Time Domain Frequency Stability". Implementation: M. A. Hopcroft, mhopeng@gmail.com, Matlab Central.'

FPSWF – Four Parameter Sine Wave Fitting

Description

.id — FPSWF

.name — Four Parameter Sine Wave Fit

.desc — Fits a sine wave to the recorded data by means of least squares fitting using 4 parameter (frequency, amplitude, phase and offset) model. An estimate of signal frequency is required. Due to non-linear characteristic, converge is not always achieved. When run in Matlab, function 'lsqnonlin' in Optimization toolbox is used. When run in GNU Octave, function 'leasqr' in GNU Octave Forge package optim is used.

.citation —

.remarks — Algorithm works essentially only for simple sine wave. Algorithm is very sensitive to distortion. Algorithm requires good estimate of signal frequency.

.license — MIT License

.requires

t — Time series of sampled data

y — Sampled values

fest — Estimate of signal frequency

.returns

f — Frequency of main signal component

A — Amplitude of main signal component

ph — Phase of main signal component

O — Offset of signal

.providesGUF — no

.providesMCM — no

Example

Four parameter sine wave fitting

Example for algorithm FPSWF.

FPSWF is an algorithm for estimating the frequency, amplitude, and phase of the sine waveform. The algorithm use least squares method. Algorithm requires good estimate of frequency.

INL-DNL – Integral and Differential Non-Linearity of ADC

Description

.id — INL-DNL

.name — Integral and Differential Non-Linearity of ADC

.desc — Calculates Integral and Differential Non-Linearity of an ADC. The histogram of measured data is used to calculate INL and DNL estimators. ADC has to sample a pure sine wave. To estimate all transition levels the amplitude of the sine wave should overdrive the full range of the ADC by at least 120

.citation — Estimators are based on Tamás Virosztek, MATLAB-based ADC testing with sinusoidal excitation signal (in Hungarian), B.Sc. Thesis, 2011. Implementation: Virosztek, T., Pálfi V., Renczes B., Kollár I., Balogh L., Sárhegyi A., Márkus J., Bilau Z. T., ADCTest project site: <http://www.mit.bme.hu/projects/adctest> 2000-2014

.remarks — Based on the ADCTest Toolbox v4.3, November 25, 2014.

.license — UNKNOWN

.requires

bitres — Bit resolution of the ADC

codes — Sampled values represented as ADC codes (not converted to voltage)

.returns

DNL — Differential Non-Linearity

.providesGUF — no
.providesMCM — no

Example

Integral and Differential Non Linearity of ADC

Example for algorithm INL-DNL

INL-DNL is an algorithm for estimating Integral and Differential Non-Linearity of an ADC. ADC has to sample a pure sine wave. To estimate all transition levels the amplitude of the sine wave should overdrive the full range of the ADC by at least 120%. If not so, non estimated transition levels will be assumed to be 0 and the results may be less accurate. As an input ADC codes are required.’;

See also ‘Virosztek, T., Pálfi V., Renczes B., Kollár I., Balogh L., Sárhegyi A., Márkus J., Bilau Z. T., ADCTest project site: <http://www.mit.bme.hu/projects/adctest> 2000-2014’;

Contents

- Generate sample data
- Call algorithm

Generate sample data

Suppose a sine wave of nominal frequency 10 Hz and nominal amplitude 1.5 V is sampled by ADC with bit resolution of 4 and full range of 1 V. First quantity `bitres` with number of bits of resolution of the ADC is prepared and put into input data structure `DI`.

```
DI = [];  
DI.bitres.v = 4;
```

Waveform is constructed. Amplitude is selected to overload the ADC.

```
t=[0:1/1e4:1-1/1e4];  
Anom = 3.5; fnom = 2; phnom = 0;  
wvfrm = Anom*sin(2*pi*fnom*t + phnom);
```

Next ADC code values are calculated. It is simulated by quantization and scaling of the sampled waveform. In real measurement code values can be obtained directly from the ADC. Suppose ADC range is -2..2.

```
codes = wvfrm ;
rmin = -2; rmax = 2;
levels = 2.^DI.bitres.v - 1;
codes(codes<rmin) = rmin;
codes(codes>rmax) = rmax;
codes = round((codes-rmin)./(rmax-rmin).*levels);
```

Now lets introduce ADC error. Instead of generating code 2 ADC erroneously generates code 3 and instead of 11 it generates 10.

```
codes(codes==2) = 3;
codes(codes==11) = 10;
codes = codes + min(codes);
```

Create quantity codes and plot a figure with sampled sine wave and codes.

```
DI.codes.v = codes;
figure
hold on
stairs(t, codes);
wvfrm = (wvfrm - rmin)./(rmax-rmin).*levels;
plot(t, wvfrm, '-r');
xlabel('t (s)')
ylabel('Codes / Voltage (scaled)');
legend('Codes generated by ADC', 'Original waveform  
scaled to match codes');
hold off
```

Call algorithm

Apply INL algorithm to the input data DI.

```
DO = qwtb('INL-DNL', DI);
```

QWTB: no uncertainty calculation

Plot results of integral non-linearity. One can clearly observe defects on codes 3 and 11.

```
figure
plot(DO.INL.v, '-x');
xlabel('Transition levels')
ylabel('INL (k)')
% Plot results of differential non-linearity. One can
% clearly observe defects on transitions 2-3 and
% 10-11.
figure
plot(DO.DNL.v, '-x');
xlabel('Code bins')
ylabel('DNL (k)')
```

SFDR – Spurious Free Dynamic Range

Description

.id — SFDR

.name — Spurious Free Dynamic Range

.desc — Calculates Spurious Free Dynamic Range of an ADC. A FFT method with Blackman windowing is used to calculate a spectrum and SFDR is estimated in decibels relative to carrier amplitude. ADC has to sample a pure sine wave. SFDR is calculated according IEEE Std 1057-2007

.citation — Implementation: Virosztek, T., Pálfi V., Renczes B., Kollár I., Balogh L., Sárhegyi A., Márkus J., Bilau Z. T., ADCTest project site: <http://www.mit.bme.hu/projects/adctest> 2000-2014

.remarks — Based on the ADCTest Toolbox v4.3, November 25, 2014.

.license — UNKNOWN

.requires

y — Sampled values

.returns

SFDRdBc — Spurious Free Dynamic Range in decibels relative to carrier (dBc)

.providesGUF — no

.providesMCM — no

Example

Spurious Free Dynamic Range by means of Fast fourier transform

Example for algorithm SFDR.

Calculates SFDR by calculating FFT spectrum.

Contents

- Generate sample data
- Call algorithm
- Display results

Generate sample data

First quantity y representing 1 second of signal containing spurious component is prepared. Main signal component has nominal frequency 1 kHz, nominal amplitude 2 V, nominal phase 1 rad and offset 1 V sampled at sampling frequency 10 kHz.

```
DI = [];  
fsnom = 1e4; Anom = 4; fnom = 100; phnom = 1; Onom =  
    0.2;  
t = [0:1/fsnom:1-1/fsnom];  
DI.y.v = Anom*sin(2*pi*fnom*t + phnom);
```

A spurious component with amplitude at 1/100 of main carrier frequency is added. Thus by definition the SFDR in dBc has to be 40.

```
DI.y.v = DI.y.v + Anom./100*sin(2*pi*fnom*3.5*t + phnom  
    );
```

Call algorithm

Use QWTB to apply algorithm SFDR to data DI.

```
DO = qwtb( 'SFDR' , DI );
```

QWTB: no uncertainty calculation

Display results

Result is the SFDR (dBc).

```
SFDR = DO.SFDRdBc.v
```

SFDR =

40.0000

PSFE – Phase Sensitive Frequency Estimator

Description

.id — PSFE

.name — Phase Sensitive Frequency Estimator

.desc — An algorithm for estimating the frequency, amplitude, and phase of the fundamental component in harmonically distorted waveforms. The algorithm minimizes the phase difference between the sine model and the sampled waveform by effectively minimizing the influence of the harmonic components. It uses a three-parameter sine-fitting algorithm for all phase calculations. The resulting estimates show up to two orders of magnitude smaller sensitivity to harmonic distortions than the results of the four-parameter sine fitting algorithm.

.citation — Lapuh, R., "Estimating the Fundamental Component of Harmonically Distorted Signals From Noncoherently Sampled Data," Instrumentation and Measurement, IEEE Transactions on , vol.64, no.6, pp.1419,1424, June 2015, doi: 10.1109/TIM.2015.2401211, URL: <http://ieeexplore.ieee.org/stamp/stamp.jsp?tp=&arnumber=7061456&isnumber=7104190>

.remarks — Very small errors, effective for harmonically distorted signals.

SINAD-ENOB – Ratio of signal to noise and distortion and Effective number of bits (in time space)

Description

.id — SINAD-ENOB

.name — Ratio of signal to noise and distortion and Effective number of bits (in time space)

.desc — Algorithm calculates Ratio of signal to noise and distortion and Effective number of bits in time space, therefore it is suitable for noncoherent measurements. Requires estimates of the main signal component parameters: frequency, amplitude, phase and offset. If these values are estimated by four parameter sine wave fit, the SINAD and ENOB will be calculated according IEEE Std 1241-2000. A large sine wave should be applied to the ADC input. Almost any error source in the sine wave input other than gain accuracy and dc offset can affect the test result.

.citation — IEEE Std 1241-2000, pages 52 - 54

.remarks —

.license — MIT License

.requires

t — time vector

y — sampled values

f — frequency of the main signal component

A — amplitude of the main signal component

ph — phase of the main signal component

O — offset of the main signal component

bitres — bit resolution of an ADC

range — Full scale range of an ADC

.returns

SINADdB — Ratio of signal to noise and distortion in decibels relative to the amplitude of the main signal component

ENOB — Effective number of bits

.providesGUF — no

.providesMCM — no

Example

Ratio of signal to noise and distortion and Effective number of bits (time space)

Example for algorithm SINAD-ENOB.

Algorithm calculates Ratio of signal to noise and distortion and Effective number of bits in time space. First signal is generated, then estimates of signal parameters are calculated by Four parameter sine wave fitting and next SINAD and ENOB are calculated. This example do not take into account a quantisation noise.

Contents

- Generate sample data
- Calculate estimates of signal parameters
- Copy results to inputs
- Calculate SINAD and ENOB
- Display results:

Generate sample data

Two quantities are prepared: t and y, representing 1 second of sinus waveform of nominal frequency 1 kHz, nominal amplitude 1 V, nominal phase 1 rad and offset 1 V sampled at sampling frequency 10 kHz.

```

DI = [];
Anom = 2; fnom = 100; phnom = 1; Onom = 0.2;
DI.t.v = [0:1/1e4:1-1/1e4];
DI.y.v = Anom*sin(2*pi*fnom*DI.t.v + phnom) + Onom;

```

Add a noise with normal distribution probability:

```

noisestd = 1e-4;
DI.y.v = DI.y.v + noisestd.*randn(size(DI.y.v));

```

Lets make an estimate of frequency 0.2 percent higher than nominal value:

```

DI.fest.v = 100.2;

```

Calculate estimates of signal parameters

Use QWTB to apply algorithm FPSWF to data DI.

```

CS.verbose = 1;
DO = qwtb('FPSWF', DI, CS);

```

*QWTB: no uncertainty calculation
Fitting started*

Local minimum found.

*Optimization completed because the **size** of the

SP-FFT – Spectrum by means of Fast Fourier Transform

Description

.id — SP-FFT

.name — Spectrum by means of Fast Fourier Transform

.desc — Calculates frequency and phase spectrum by means of Fast Fourier Transform algorithm. Result is normalized.

.citation —

.remarks —

.license — MIT License

.requires

 y — Sampled values

 fs — Sampling frequency

.returns

 f — Frequency series

 A — Amplitude series

 ph — Phase series

.providesGUF — no

.providesMCM — no

Example

Signal Spectrum by means of Fast fourier transform

Example for algorithm SP-FFT.

Calculates frequency and phase spectrum by means of Fast Fourier Transform algorithm. Result is normalized.

Contents

- Generate sample data
- Call algorithm
- Display results

Generate sample data

Two quantities are prepared: y and fs , representing 1 second of signal containing 5 harmonic components and one inter-harmonic component. Main signal component has nominal frequency 1 kHz, nominal amplitude 2 V, nominal phase 1 rad and offset 1 V sampled at sampling frequency 10 kHz.

```
DI = [];  
fsnom = 1e4; Anom = 2; fnom = 100; phnom = 1; Onom =  
    0.2;  
t = [0:1/fsnom:1-1/fsnom];  
DI.y.v = Anom*sin(2*pi*fnom*t + phnom);  
for i = 2:45  
    DI.y.v = DI.y.v + Anom./i*sin(2*pi*fnom*i*t +  
        phnom + i - 1);  
end  
DI.y.v = DI.y.v + 1*sin(2*pi*fnom*1.456*t + phnom);  
DI.fs.v = fsnom;
```

Call algorithm

Use QWTB to apply algorithm SP-FFT to data DI.

```
DO = qwtb('SP-FFT', DI);
```

QWTB: no uncertainty calculation

Display results

Results is the amplitude and phase spectrum.

```
figure
plot(DO.f.v, DO.A.v, '-x')
xlabel('f (Hz)'); ylabel('A (V)'); title('Amplitude
    spectrum of the signal');
figure
plot(DO.f.v, DO.ph.v, '-x')
xlabel('f (Hz)'); ylabel('phase (rad)'); title('Phase
    spectrum of the signal');
```
